## Historical background / Motivation:

- Huge amount of **data**, that should **automatically** be processed,
- Mathematics provides general solutions, solutions are i.e. **not for a given problem**,
- Need for “science”, that uses mathematics machinery for solving **practical** problems.

## Machine learning

Collection of methods (from statistics, probability theory) to solve problems **met in practice**.

- noise filtering for
  - non-linear regression and/or
  - non-Gaussian noise
- Classification:
  - binary,
  - multiclass,
  - partially labelled
- Clustering,
- Inversion problems,
- density estimation, novelty detection.

Generally, we need to **model the data**,

- Real world: there “is” a function  $y = f(x)$
- Observation process: a corrupted datum is collected for a sample  $x_n$ :

$$t_n = y_n + \epsilon \quad \text{additive noise}$$

$$t_n = h(y_n, \epsilon) \quad h \text{ distortion function}$$

- **Problem:** find function  $y = f(x)$

- We have the **data set**  $\mathcal{D} = \{(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_N, y_N)\}$ .

- Consider a function class:

$$(1) \quad \mathcal{F} = \{\mathbf{w}^T \mathbf{x} + b \mid \mathbf{w} \in \mathbb{R}^d, b \in \mathbb{R}\}$$

$$(2) \quad \mathcal{F} = \left\{ a_0 + \sum_{k=1}^K a_k \sin(2\pi kx) + \sum_{k=1}^K b_k \cos(2\pi kx) \right.$$

$$\left. \mid \mathbf{a}, \mathbf{b} \in \mathbb{R}^K, a_0 \in \mathbb{R} \right\}$$

- Assume an observation process:

$$y_n = f(\mathbf{x}_n) + \epsilon \quad \text{with } \epsilon \sim N(0, \sigma^2).$$

1 The **data set**:  $\mathcal{D} = \{(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_N, y_N)\}$ .

2 Assume a function class:

$$\mathcal{F} = \{f(\mathbf{x}, \boldsymbol{\theta}) \mid \boldsymbol{\theta} \in \mathbb{R}^P\}$$

$\mathcal{F}$  – polynomial, etc.

3 Assume an observation process. Define a **loss function**:

$$L(y_n, f(\mathbf{x}_n, \boldsymbol{\theta}))$$

For the Gaussian noise:

$$L(y_n, f(\mathbf{x}_n, \boldsymbol{\theta})) = (y_n - f(\mathbf{x}_n, \boldsymbol{\theta}))^2.$$

Estimating parameters:

Finding the **optimal value to  $\theta$** :

$$\theta^* = \arg \min_{\theta \in \Omega} L(\mathcal{D}, \theta)$$

where

- $\Omega$  is the domain of the parameters.
- $L(\mathcal{D}, \theta)$  is a “loss function” for the data set.

Example:

$$L(\mathcal{D}, \theta) = \sum_{n=1}^N L(y_n, f(\mathbf{x}_n, \theta))$$

$L(\mathcal{D}, \theta)$  – (log)likelihood function.

Maximum likelihood estimation of the model:

$$\theta^* = \arg \min_{\theta \in \Omega} L(\mathcal{D}, \theta)$$

Example – quadratic regression:

$$L(\mathcal{D}, \theta) = \sum_{n=1}^N (y_n - f(\mathbf{x}_n, \theta))^2 \quad \text{– factorisation}$$

Drawback: can produce **perfect** fit to the data – **over-fitting**.

$$h = \theta_0 + \theta_1 w + \theta_2 w^2 + \theta_3 w^3 + \dots$$

Assume:

linear model for the  $\mathbf{x} \rightarrow y$  relation

$$f(\mathbf{x}_n|\boldsymbol{\theta}) = \sum_{\ell=1}^d \theta_{\ell} x_{\ell}$$

with  $\mathbf{x} = [1, x, x^2, \log(x), \dots]^T$

quadratic loss for  $\mathcal{D} = \{(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_N, h_N)\}$

$$E_2(\mathcal{D}|f) = \sum_{n=1}^N (y_n - f(\mathbf{x}_n|\boldsymbol{\theta}))^2$$

## Minimisation:

$$\begin{aligned}\sum_{n=1}^N (y_n - f(\mathbf{x}_n|\boldsymbol{\theta}))^2 &= (\mathbf{y} - \mathbf{X}\boldsymbol{\theta})^T (\mathbf{y} - \mathbf{X}\boldsymbol{\theta}) \\ &= \boldsymbol{\theta}^T \mathbf{X}^T \mathbf{X} \boldsymbol{\theta} - 2\boldsymbol{\theta}^T \mathbf{X}^T \mathbf{y} + \mathbf{y}^T \mathbf{y}\end{aligned}$$

## Solution:

$$\begin{aligned}0 &= 2\mathbf{X}^T \mathbf{X} \boldsymbol{\theta} - 2\mathbf{X}^T \mathbf{y} \\ \boldsymbol{\theta} &= (\mathbf{X}^T \mathbf{X})^{-1} \mathbf{X}^T \mathbf{y}\end{aligned}$$

where  $\mathbf{y} = [y_1, \dots, y_N]^T$  and  $\mathbf{X} = [\mathbf{x}_1, \dots, \mathbf{x}_N]^T$  are the transformed data.

## Generalised linear models:

- Use a *set of functions*  $\Phi = [\phi_1(\cdot), \dots, \phi_M(\cdot)]$ .
- Project the inputs into the space spanned by  $\text{Im}(\Phi)$ .
- Have a parameter vector of length  $M$ :  
 $\theta = [\theta_1, \dots, \theta_M]^T$ .
- The model is  $\left\{ \sum_m \theta_m \phi_m(\mathbf{x}) \mid \theta_m \in \mathbb{R} \right\}$ .
- The optimal parameter vector is:

$$\theta^* = (\Phi^T \Phi)^{-1} \Phi^T \mathbf{y}$$

- There are many candidate **model families**:
  - the degree of polynomials specifies a model family;
  - the rank of a Fourier expansion;
  - the mixture of  $\{\log, \sin, \cos, \dots\}$  also a *family*;
- Selecting the “best family” is a difficult *modelling* problem.
- In maximum likelihood there is no control on how good a family is when processing a *given* data-set.

*Smaller number of parameters than  $\sqrt{\#data}$ .*

- Generalised linear model powerful – it can be extremely complex;
  - With no complexity control, overfitting problem.
- **Aim:** to include **knowledge** in the inference process.
- Our beliefs are reflected by the choice of the candidate functions.

## Goal:

- Prior knowledge specification using probabilities;
- Using probability theory for consistent estimation;
- Encode the observation noise in the model;

## Probabilistic data description:

- **How likely** is that  $\theta$  generated the data:

$$y = f(\mathbf{x}) \quad \Leftrightarrow \quad y - f(\mathbf{x}) \sim \delta_0$$

$$y = f(\mathbf{x}) + \epsilon \quad \Leftrightarrow \quad y - f(\mathbf{x}) \sim N_\epsilon$$

- **Gaussian noise:**  $y - f(\mathbf{x}) \sim N(0, \sigma^2)$

$$P(y|f(\mathbf{x})) = \frac{1}{\sqrt{2\pi}\sigma} \exp \left[ -\frac{(y - f(\mathbf{x}))^2}{2\sigma^2} \right]$$

## William of **Ockham** (1285–1349) principle

Entities should not be multiplied beyond necessity.

Also known as (wiki...):

“Principle of simplicity” – KISS,

“When you hear hoofbeats, think horses, not zebras”.

Simple models  $\approx$  small number of parameters.

$L_0$  norm

$L_2$  norm

$\Leftarrow$

## Probabilistic representation:

$$p_0(\theta) \propto \exp \left[ -\frac{\|\theta\|_2^2}{2\sigma_0^2} \right]$$

M.A.P. – **probabilities** assigned to

- $\mathcal{D}$  – via the log-likelihood function:

$$P(y_n | \mathbf{x}_n, \theta, \mathcal{F}) \propto \exp[-L(y_n, f(\mathbf{x}_n, \theta))]$$

- $\theta$  – prior probabilities:

$$p_0(\theta) \propto \exp\left[-\frac{\|\theta\|^2}{2\sigma_0^2}\right]$$

- **A**-posteriori probability:

$$p(\theta | \mathcal{D}, \mathcal{F}) = \frac{P(\mathcal{D} | \theta) p_0(\theta)}{p(\mathcal{D} | \mathcal{F})}$$

$p(\mathcal{D} | \mathcal{F})$  – probability of the **data** for a given family.

M.A.P. – **probabilities** assigned to

- $\mathcal{D}$  – via the log-likelihood function:

$$P(y_n | \mathbf{x}_n, \boldsymbol{\theta}, \mathcal{F}) \propto \exp[-L(y_n, f(\mathbf{x}_n, \boldsymbol{\theta}))]$$

- $\boldsymbol{\theta}$  – prior probabilities:

$$p_0(\boldsymbol{\theta}) \propto \exp\left[-\frac{\|\boldsymbol{\theta}\|^2}{2\sigma_0^2}\right]$$

- A-posteriori probability:

$$p(\boldsymbol{\theta} | \mathcal{D}, \mathcal{F}) = \frac{P(\mathcal{D} | \boldsymbol{\theta}) p_0(\boldsymbol{\theta})}{p(\mathcal{D} | \mathcal{F})}$$

$p(\mathcal{D} | \mathcal{F})$  – probability of the **data** for a given family.

M.A.P. – **probabilities** assigned to

- $\mathcal{D}$  – via the log-likelihood function:

$$P(y_n | \mathbf{x}_n, \boldsymbol{\theta}, \mathcal{F}) \propto \exp[-L(y_n, f(\mathbf{x}_n, \boldsymbol{\theta}))]$$

- $\boldsymbol{\theta}$  – prior probabilities:

$$p_0(\boldsymbol{\theta}) \propto \exp\left[-\frac{\|\boldsymbol{\theta}\|^2}{2\sigma_0^2}\right]$$

- **A**-posteriori probability:

$$p(\boldsymbol{\theta} | \mathcal{D}, \mathcal{F}) = \frac{P(\mathcal{D} | \boldsymbol{\theta}) p_0(\boldsymbol{\theta})}{p(\mathcal{D} | \mathcal{F})}$$

$p(\mathcal{D} | \mathcal{F})$  – probability of the **data** for a given family.

**M.A.P. estimation** – finds  $\theta$  with largest probability:

$$\theta_{MAP}^* = \arg \max_{\theta \in \Omega} p(\theta | \mathcal{D}, \mathcal{F})$$

**Example:** with  $L(y_n, f(\mathbf{x}_n, \theta))$  and Gaussian prior:

$$\theta_{MAP}^* = \operatorname{argmax}_{\theta \in \Omega} K - \frac{1}{2} \sum_n L(y_n, f(\mathbf{x}_n, \theta)) - \frac{\|\theta\|^2}{2\sigma_0^2}$$

$$\sigma_0^2 = \infty \implies \text{maximum likelihood.}$$

after a change of sign and  $\max \rightarrow \min$

$$\theta_{MAP}^* = \operatorname{argmax}_{\theta \in \Omega} K - \frac{1}{2} \sum_n E_2(y_n, f(\mathbf{x}_n, \theta)) - \frac{\|\theta\|^2}{2\sigma_0^2}$$

Transform into vector notation:

$$\theta_{MAP}^* = \operatorname{argmax}_{\theta \in \Omega} K - \frac{1}{2} (\mathbf{y} - \mathbf{X}\theta)^T (\mathbf{y} - \mathbf{X}\theta) - \frac{\theta^T \theta}{2\sigma_0^2}$$

solve for  $\theta$  by differentiation:

$$\mathbf{X}^T (\mathbf{y} - \mathbf{X}\theta) - \frac{1}{\sigma_0^2} I_d \theta = 0$$

$$\theta_{MAP}^* = \left( \mathbf{X}^T \mathbf{X} + \frac{1}{\sigma_0^2} I_d \right)^{-1} \mathbf{X}^T \mathbf{y}$$

## Maximum a-posteriori models:

- Allow for the inclusion of prior knowledge;
- May protect against overfitting;
- Can measure the fitness of the family to the data;  
Procedure called **M.L. type II**.

**Idea:** instead of computing the most probable value of  $\theta$ , we can measure the **fit** of the model  $\mathcal{F}$  to the data  $\mathcal{D}$ .

$$\begin{aligned} P(\mathcal{D}|\mathcal{F}) &= \sum_{\theta_\ell \in \Omega} p(\mathcal{D}, \theta_\ell | \mathcal{F}) \\ &= \sum_{\theta_\ell \in \Omega} p(\mathcal{D} | \theta_\ell, \mathcal{F}) p_0(\theta_\ell | \mathcal{F}) \end{aligned}$$

**Gaussian noise and polynomial of order  $K$ :**

$$\begin{aligned} \log(P(\mathcal{D}|\mathcal{F})) &= \log \left( \int_{\Omega_\theta} d\theta \frac{p(\mathcal{D} | \theta, \mathcal{F}) p_0(\theta | \mathcal{F})}{p(\mathcal{D} | \mathcal{F})} \right) = \log(N(\mathbf{y} | 0, \Sigma_X)) \\ &= -\frac{1}{2} \left( N \log(2\pi) + \log |\Sigma_X| + \mathbf{y}^T \Sigma_X^{-1} \mathbf{y} \right) \end{aligned}$$

where

$$\Sigma_X = I_N \sigma_n^2 + \mathbf{X} \Sigma_0 \mathbf{X}^T \quad \text{with} \quad \mathbf{X} = [\mathbf{x}^0, \mathbf{x}^1, \dots, \mathbf{x}^K]$$
$$\Sigma_0 = \text{diag}(\sigma_0^2, \sigma_1^2, \dots, \sigma_K^2)$$

- M.L. and M.A.P. estimates provide **single** solutions.
- Point estimates lack the assessment of un/certainty.
- Better solution:  
for a query  $\mathbf{x}_*$ , the system output is **probabilistic**:

$$\mathbf{x}_* \Rightarrow p(y_* | \mathbf{x}_*, \mathcal{F})$$

- Tool:  
go beyond the M.A.P. solution and use the **a-posteriori distribution** of the parameters.

We again use Bayes' rule:

$$p(\theta|\mathcal{D}, \mathcal{F}) = \frac{P(\mathcal{D}|\theta)p_0(\theta)}{p(\mathcal{D}|\mathcal{F})} \quad \text{with } p(\mathcal{D}|\mathcal{F}) = \int_{\Omega} d\theta P(\mathcal{D}|\theta)p_0(\theta).$$

and **exploit** the whole posterior distribution of the parameters.

## A-posteriori parameter estimates

We operate with  $p_{\text{post}}(\theta) \stackrel{\text{def}}{=} p(\theta|\mathcal{D}, \mathcal{F})$  and use the total probability rule:

$$p(y_*|\mathcal{D}, \mathcal{F}) = \sum_{\theta \ell \in \Omega_{\theta}} p(y_*|\theta_{\ell}, \mathcal{F}) p_{\text{post}}(\theta_{\ell})$$

in assessing system output.

Given the data  $\mathcal{D} = \{(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_N, y_N)\}$  estimate the linear fit:

$$y = \theta_0 + \sum_{i=1}^d \theta_i x_i = \begin{bmatrix} \theta_0 \\ \theta_1 \\ \vdots \\ \theta_d \end{bmatrix}^T \begin{bmatrix} 1 \\ x_1 \\ \vdots \\ x_d \end{bmatrix} \stackrel{\text{def}}{=} \boldsymbol{\theta}^T \mathbf{x}$$

Gaussian distributions noise and prior:

$$\epsilon = y_n - \boldsymbol{\theta}^T \mathbf{x}_n \sim \mathcal{N}(0, \sigma_n^2)$$
$$\mathbf{w} \sim \mathcal{N}(0, \boldsymbol{\Sigma}_0)$$

**Goal:** compute the posterior distribution  $p_{\text{post}}(\boldsymbol{\theta})$ .

$$p_{\text{post}}(\boldsymbol{\theta}) \propto p_0(\boldsymbol{\theta}) p(\mathcal{D}|\boldsymbol{\theta}, \mathcal{F}) = p_0(\boldsymbol{\theta} | \boldsymbol{\Sigma}_0) \prod_{n=1}^N P(y_n | \boldsymbol{\theta}^T \mathbf{x}_n)$$

$$\begin{aligned} -2 \log(p_{\text{post}}(\boldsymbol{\theta})) &= K_{\text{post}} + \frac{1}{\sigma_n^2} (\mathbf{y} - \mathbf{X}\boldsymbol{\theta})^T (\mathbf{y} - \mathbf{X}\boldsymbol{\theta}) + \boldsymbol{\theta}^T \boldsymbol{\Sigma}_0^{-1} \boldsymbol{\theta} \\ &= \boldsymbol{\theta}^T \left( \frac{1}{\sigma_n^2} \mathbf{X}^T \mathbf{X} + \boldsymbol{\Sigma}_0^{-1} \right) \boldsymbol{\theta} - \frac{2}{\sigma_n^2} \boldsymbol{\theta}^T \mathbf{X}^T \mathbf{y} + K'_{\text{post}} \\ &= (\boldsymbol{\theta} - \boldsymbol{\mu}_{\text{post}})^T \boldsymbol{\Sigma}_{\text{post}}^{-1} (\boldsymbol{\theta} - \boldsymbol{\mu}_{\text{post}}) + K''_{\text{post}} \end{aligned}$$

and by identification

$$\boldsymbol{\Sigma}_{\text{post}} = \left( \frac{1}{\sigma_n^2} \mathbf{X}^T \mathbf{X} + \boldsymbol{\Sigma}_0^{-1} \right)^{-1} \quad \text{and} \quad \boldsymbol{\mu}_{\text{post}} = \boldsymbol{\Sigma}_{\text{post}} \frac{\mathbf{X}^T \mathbf{y}}{\sigma_n^2}$$

## Bayesian linear model

The posterior distribution for the parameters is a Gaussian with parameters

$$\Sigma_{\text{post}} = \left( \frac{1}{\sigma_n^2} \mathbf{X}^T \mathbf{X} + \Sigma_0^{-1} \right)^{-1} \quad \text{and} \quad \mu_{\text{post}} = \Sigma_{\text{post}} \frac{\mathbf{X}^T \mathbf{y}}{\sigma_n^2}$$

**Point estimates** from keeping :

- M.L. if we take  $\Sigma_0 \rightarrow \infty$  and considering only  $\mu_{\text{post}}$ .
- M.A.P if we approximate the distribution with a single value at the maximum, *i.e.*  $\mu_{\text{post}}$ .

## Prediction for new values $\mathbf{x}_*$ :

- use the likelihood  $P(y_* | \mathbf{x}_*, \theta, \mathcal{F})$ ,
- and the **posterior** for  $\theta$
- and Bayes' rule.

The steps:

$$\begin{aligned} p(y_* | \mathbf{x}_*, \mathcal{D}, \mathcal{F}) &= \int_{\Omega_\theta} d\theta p(y_* | \mathbf{x}_*, \theta, \mathcal{F}) p_{\text{post}}(\theta | \mathcal{D}, \mathcal{F}) \\ &= \int_{\Omega_\theta} d\theta \exp \left[ -\frac{1}{2} \left( K_* + \frac{(y_* - \theta^T \mathbf{x}_*)^2}{\sigma_n^2} + (\theta - \mu_{\text{post}})^T \Sigma_{\text{post}}^{-1} (\theta - \mu_{\text{post}}) \right) \right] \\ &= \int_{\Omega_\theta} d\theta \exp \left[ -\frac{1}{2} \left( K_* + \frac{y_*^2}{\sigma_n^2} - \mathbf{a}^T \mathbf{C}^{-1} \mathbf{a} + Q(\theta) \right) \right] \end{aligned}$$

where

$$\mathbf{a} = \frac{\mathbf{x}_* y_*}{\sigma_n^2} + \Sigma_{\text{post}}^{-1} \mu_{\text{post}} \quad \mathbf{C} = \frac{\mathbf{x}_* \mathbf{x}_*^T}{\sigma_n^2} + \Sigma_{\text{post}}$$

Integrating out the quadratic in  $\theta$ :

**Predictive distribution at  $\mathbf{x}_*$**

$$p(y_* | \mathbf{x}_*, \mathcal{D}, \mathcal{F}) = \exp \left[ -\frac{1}{2} \left( K_* + \frac{(y_* - \mathbf{x}_*^T \boldsymbol{\mu}_{\text{post}})^2}{\sigma_n^2 + \mathbf{x}_*^T \boldsymbol{\Sigma}_{\text{post}}^{-1} \mathbf{x}_*} \right) \right]$$
$$= \mathcal{N} \left( y_* \mid \mathbf{x}_*^T \boldsymbol{\mu}_{\text{post}}, \sigma_n^2 + \mathbf{x}_*^T \boldsymbol{\Sigma}_{\text{post}} \mathbf{x}_* \right)$$

With the predictive distribution we:

- measure the variance of the prediction for each point:  
 $\sigma_*^2 = \sigma_n^2 + \mathbf{x}_*^T \boldsymbol{\Sigma}_{\text{post}} \mathbf{x}_*$ ;
- sample from the parameters and plot the candidate predictors.

When computing  $p_{\text{post}}(\theta | \mathcal{D}, \mathcal{F})$  we assumed that the posterior **can be represented** analytically.

This is not the case.

Approximations are needed for the

- posterior distribution
- predictive distribution

In Bayesian modelling an important issue is **how** we approximate the posterior distribution.

- Data can be unlabeled, *i.e.* no values  $y$  are associated to an input  $x$ .
- We want to “extract” information from  $\mathcal{D} = \{\mathbf{x}_1, \dots, \mathbf{x}_N\}$ .
- We assume that the data – although high-dimensional – spans a **manifold** of a much smaller dimension.
- Task is to find the subspace corresponding to the *data span*.

- Simple data structure.
- Spherical cluster that is:
  - translated;
  - scaled;
  - rotated.

We aim to find the principal directions of the data spread.

## Principal direction:

the direction  $u$  along which the data preserves most of its *variance*.

## Principal direction:

$$\mathbf{u} = \operatorname{argmax}_{\|\mathbf{u}\|=1} \frac{1}{2N} \sum_{n=1}^N (\mathbf{u}^T \mathbf{x}_n - \mathbf{u} \bar{x})^2$$

we pre-process:  $\bar{\mathbf{x}} = \mathbf{0}$ . Replacing the empirical covariance with  $\Sigma_{\mathbf{x}}$ :

$$\begin{aligned} \mathbf{u} &= \operatorname{argmax}_{\|\mathbf{u}\|=1} \frac{1}{2N} \sum_{n=1}^N (\mathbf{u}^T \mathbf{x}_n - \mathbf{u} \bar{x})^2 \\ &= \operatorname{argmax}_{\mathbf{u}, \lambda} \frac{1}{2} \mathbf{u}^T \Sigma_{\mathbf{x}} \mathbf{u} - \lambda (\|\mathbf{u}\|^2 - 1) \end{aligned}$$

with  $\lambda$  the Lagrange multiplier. Differentiating w.r.t  $\mathbf{u}$ :

$$\Sigma_{\mathbf{x}} \mathbf{u} - \lambda \mathbf{u} = \mathbf{0}$$

The optimum solution **must obey**:

$$\Sigma_x \mathbf{u} = \lambda \mathbf{u}$$

The **eigendecomposition** of the covariance matrix.

$(\lambda_*, \mathbf{u}_*)$  is an eigenvalue, eigenvector of the system.

If we replace back, the value of the expression is  $\lambda_*$ .

$\Rightarrow$

Optimal solution when  $\lambda_* = \lambda_{max}$ .

## Principal direction:

The eigenvector  $\mathbf{u}_{max}$  corresponding to the largest eigenvalue of the system.

## How is this used in data mining?

Assume that data is:

- jointly Gaussian:

$$\mathbf{x} = \mathbf{N}(\mathbf{m}_x, \Sigma_x),$$

- high-dimensional;
- only few (2) directions are relevant.

## How is this used in data mining?

- Subtracting mean.
- Eigendecomposition.
- Selecting the  $K$  eigenvectors corresponding to the  $K$  largest values.
- Computing the  $K$  projections:  $z_{nl} = \mathbf{x}_n^T \mathbf{u}_l$ .

The projection using matrix  $\mathbf{P} \stackrel{\text{def}}{=} [\mathbf{u}_1, \dots, \mathbf{u}_K]^T$ :

$$\mathbf{Z} = \mathbf{XP}$$

and  $\mathbf{z}_n$  can be used as a compact representation of  $\mathbf{x}_n$ .

## Reconstruction:

$$\mathbf{x}'_n = \sum_{\ell=1}^K z_{n\ell} \mathbf{u}_\ell \quad \text{or, with matrix notation: } \mathbf{X}' = \mathbf{Z}\mathbf{P}^T$$

## PCA projection analysis:

$$\begin{aligned} E_{PCA} &= \frac{1}{N^2} \sum_{n=1}^N (\mathbf{x}_n - \mathbf{x}'_n)^2 = \frac{1}{N^2} \text{tr} \left[ (\mathbf{X} - \mathbf{X}')^T (\mathbf{X} - \mathbf{X}') \right] \\ &= \text{tr} \left[ \boldsymbol{\Sigma}_x - \mathbf{P}^T \boldsymbol{\Sigma}_z \mathbf{P} \right] \\ &= \text{tr} \left[ \mathbf{U} (\text{diag}(\lambda_1, \dots, \lambda_d) - \text{diag}(\lambda_1, \dots, \lambda_K, 0, \dots)) \mathbf{U}^T \right] \\ &= \text{tr} \left[ \mathbf{U}^T \mathbf{U} \text{diag}(0, \dots, 0, \lambda_{K+1}, \dots, \lambda_d) \right] \\ &= \sum_{\ell=1}^{d-K} \lambda_{K+\ell} \end{aligned}$$

## PCA reconstruction error:

The error made using the PCA directions:

$$E_{PCA} = \sum_{\ell=1}^{d-K} \lambda_{K+\ell}$$

## PCA properties:

- PCA system orthonormal:  $\mathbf{u}_\ell^T \mathbf{u}_r = \delta_{\ell-r}$
- Reconstruction **fast**.
- Spherical assumption critical.

**USPS** digits – testbed for several models.

## USPS characteristics:

- handwritten data centered and scaled;
- $\approx 10.000$  items of  $16 \times 16$  grayscale images;

We plot

$k_r = \sum_{\ell=1}^r \lambda_{\ell}$  -  
normalised

## Conclusion for the USPS set:

- The normalised  $\lambda_1 = 0.24 \Rightarrow \mathbf{u}_1$  accounts for 24% of the data.
- at  $\approx 10$  more than 70% of variance is explained.
- at  $\approx 50$  more than 98%  
 $\Rightarrow$  50 numbers instead of 256.

## Start from the PCA:

$$\mathbf{x} = \mathbf{P}\mathbf{z}$$

is a **generative model** for the data.

We assumed that

- $\mathbf{z}$  i.i.d. Gaussian random variables  $\mathbf{z} \sim \mathcal{N}(\mathbf{0}, \text{diag}(\lambda_\ell))$ ;
- $\Rightarrow \mathbf{x}$  are not independent;
- $\Rightarrow$

$\mathbf{z}$  are **Gaussian** sources;

## In most of real data:

- Sources are **not Gaussian**.
- But sources are **independent**.
- **We exploit that!**

The following model assumption:

$$x = As$$

where

- $z$  independent **sources**;
- $A$  linear **mixing matrix**;

Looking for matrix  $B$  that recovers the sources:

$$s' \stackrel{\text{def}}{=} Bx = B(As) = (BA)s$$

*i.e.*  $(BA)$  is a permutation and scaling  
but retains **independence**.

In practice:

$$\mathbf{s}' \stackrel{\text{def}}{=} \mathbf{B}\mathbf{x}$$

with  $\mathbf{s} = [s_1, \dots, s_K]$  all independent sources.

**Independence test:** the KL-divergence between the **joint distribution** and the **marginals**

$$\mathbf{B} = \underset{\mathbf{B} \in \text{SO}_d}{\text{argmin}} \text{KL} (p(s_1, s_2) || p(s_1)p(s_2))$$

where  $\text{SO}_d$  is the group of matrices with  $|\mathbf{B}| = 1$ .

In ICA we are looking for matrix  $\mathbf{B}$  that minimises:

$$\sum_{\ell} \int_{\Omega_{\ell}} ds_{\ell} \log p(s_{\ell}) - \int_{\Omega_{\ell}} d\mathbf{s} \log(p(s_1, \dots, s_d))$$

## Kullback-Leibler divergence

$$\text{KL}(p||q) = \sum_x p(x) \log \frac{p(x)}{q(x)}$$

- is zero only and only if  $p = q$ ,
- is *not* a measure of distance (but cloooooose to it!),
- Efficient when exponential families are used.

## Short proof:

$$\begin{aligned} 0 &= \log 1 = \log \left( \sum_x q(x) \right) = \log \left( \sum_x p(x) \frac{q(x)}{p(x)} \right) \\ &\geq \sum_x p(x) \log \left( \frac{q(x)}{p(x)} \right) = -\text{KL}(p||q) \end{aligned}$$

$$\Rightarrow \text{KL}(p||q) \geq 0$$

## Applications:

- **Coctail party problem;**  
Separates noisy and multiple sources from multiple observations.
- **Fetus ECG;**  
Separation of the ECG signal of a fetus from its mother's ECG.
- **MEG recordings;**  
Separation of MEG "sources".
- **Financial data;**  
Finding hidden factors in financial data.
- **Noise reduction;**  
Noise reduction in natural images.
- **Interference removal;**  
Interference removal from CDMA – Code-division multiple access – communication systems.

- The data structure is **more complex**.
- More than a single source for data.

## The mixture model:

$$P(\mathbf{x}|\Sigma) = \sum_{k=1}^K \pi_k p_k(\mathbf{x}|\mu_k, \Sigma_k) \quad (1)$$

where:

$\pi_1, \dots, \pi_K$  – mixing components.

$p_k(\mathbf{x}|\mu_k, \Sigma_k)$  – density of a component.

The components are usually called clusters.

The generation process reflects the assumptions about the model.

## The data generation:

- first we select **from which** component,
- then we sample from the component's density function.

When modelling data we **do not know**:

- Which point belongs to which cluster.
- What are the parameters for each density function.

- The longer the duration, the longer the interval.
- The linear relation  $l = \theta_0 + \theta_1 d$  is not the best.
- There are only a very few eruptions lasting  $\approx 3$  minutes.

# The mixture model

## Assumptions:

- We know the family of individual density functions:  
These density functions are parametrised with a few parameters.
- The densities are easily identifiable:  
If we knew which data belongs to which cluster, the density function is easily identifiable.

**Gaussian densities** are often used – fulfill both “conditions”.

## The Gaussian mixture model:

$$p(\mathbf{x}) = \pi_1 N_1(\mathbf{x}|\boldsymbol{\mu}_1, \boldsymbol{\Sigma}_1) + \pi_2 N_2(\mathbf{x}|\boldsymbol{\mu}_2, \boldsymbol{\Sigma}_2)$$

for **known** densities  
(centres and ellipses):

$$p(\mathbf{x}_n|k) = \frac{N_k(\mathbf{x}_n|\boldsymbol{\mu}_k, \boldsymbol{\Sigma}_k) p(k)}{\sum_{\ell} N_{\ell}(\mathbf{x}_n|\boldsymbol{\mu}_{\ell}, \boldsymbol{\Sigma}_{\ell}) p(\ell)}$$

i.e. we know the **probability** that data comes from cluster  $k$   
(shades from red to green).

For  $\mathcal{D}$ :

$\mathbf{x}$	$p(\mathbf{x} 1)$	$p(\mathbf{x} 2)$
$\mathbf{x}_1$	$\gamma_{11}$	$\gamma_{12}$
$\vdots$	$\vdots$	$\vdots$
$\mathbf{x}_N$	$\gamma_{N1}$	$\gamma_{N2}$

$\gamma_{\ell n}$  – responsibility of  $\mathbf{x}_n$  in cluster  $\ell$ .

When  $\gamma_{n\ell}$  known, the parameters are computed using the data weighted by their responsibilities:

$$(\boldsymbol{\mu}_k, \boldsymbol{\Sigma}_k) = \underset{\boldsymbol{\mu}, \boldsymbol{\Sigma}}{\operatorname{argmax}} \prod_{n=1}^N (\mathbb{N}_k(\mathbf{x}_n | \boldsymbol{\mu}, \boldsymbol{\Sigma}))^{\gamma_{nk}}$$

for all  $k$ .

This means:

$$(\boldsymbol{\mu}_k, \boldsymbol{\Sigma}_k) \leftarrow \sum_n \gamma_{nk} \log \mathbb{N}(\mathbf{x}_n | \boldsymbol{\mu}, \boldsymbol{\Sigma})$$

**When making inference**

Have to find the responsibility vector **and** the parameters of the mixture.

When  $\gamma_{nl}$  known, the parameters are computed using the data weighted by their responsibilities:

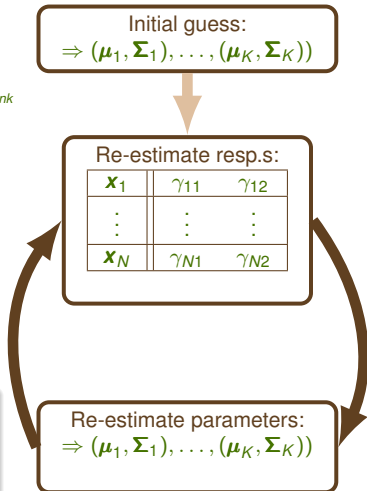

$$(\boldsymbol{\mu}_k, \boldsymbol{\Sigma}_k) = \underset{\boldsymbol{\mu}, \boldsymbol{\Sigma}}{\operatorname{argmax}} \prod_{n=1}^N (\mathbb{N}_k(\mathbf{x}_n | \boldsymbol{\mu}, \boldsymbol{\Sigma}))^{\gamma_{nk}}$$

for all  $k$ .

This means:

$$(\boldsymbol{\mu}_k, \boldsymbol{\Sigma}_k) \leftarrow \sum_n \gamma_{nk} \log \mathbb{N}(\mathbf{x}_n | \boldsymbol{\mu}, \boldsymbol{\Sigma})$$

Given data  $\mathcal{D}$ :

**When making inference**

Have to find the responsibility vector **and** the parameters of the mixture.

$$(\boldsymbol{\pi}, \boldsymbol{\Theta}) = \operatorname{argmax} \sum_n \log \left[ \sum_{\ell} \pi_{\ell} \mathcal{N}_{\ell}(\mathbf{x}_n | \boldsymbol{\mu}_{\ell}, \boldsymbol{\Sigma}_{\ell}) \right]$$

$\boldsymbol{\Theta} = [\boldsymbol{\mu}_1, \boldsymbol{\Sigma}_1, \dots, \boldsymbol{\mu}_K, \boldsymbol{\Sigma}_K]$  is the vector of parameters;  
 $\boldsymbol{\pi} = [\pi_1, \dots, \pi_K]$  the shares of the factors;

## Problem with optimisation:

The parameters are not separable due to the sum within the logarithm.

## Solution:

Use an approximation.

$$\begin{aligned}\log P(\mathcal{D}|\boldsymbol{\pi}, \boldsymbol{\Theta}) &= \sum_n \log \left[ \sum_{\ell} \pi_{\ell} N_{\ell}(\mathbf{x}_n | \boldsymbol{\mu}_{\ell}, \boldsymbol{\Sigma}_{\ell}) \right] \\ &= \sum_n \log \left[ \sum_{\ell} p_{\ell}(\mathbf{x}_n, \ell) \right]\end{aligned}$$

**Use Jensen's inequality:**

$$\begin{aligned}\log \left( \sum_{\ell} p_{\ell}(\mathbf{x}_n, \ell | \theta_{\ell}) \right) &= \log \left( \sum_{\ell} q_n(\ell) \frac{p_{\ell}(\mathbf{x}_n, \ell | \theta_{\ell})}{q_n(\ell)} \right) \\ &\geq \sum_{\ell} q_n(\ell) \log \left( \frac{p_{\ell}(\mathbf{x}_n, \ell)}{q_n(\ell)} \right)\end{aligned}$$

for **any**  $[q_n(1), \dots, q_n(\ell)]$ .

## Jensen's Inequality

For any concave  $f(z)$ , any  $z_1$  and  $z_2$ , and any  $\gamma_1, \gamma_2 > 0$  such that  $\gamma_1 + \gamma_2 = 1$ :

$$f(\gamma_1 z_1 + \gamma_2 z_2) \geq \gamma_1 f(z_1) + \gamma_2 f(z_2)$$

$$\log \left( \sum_{\ell} p_{\ell}(\mathbf{x}_n, \ell | \theta_{\ell}) \right) \geq \sum_{\ell} q_n(\ell) \log \left( \frac{p_{\ell}(\mathbf{x}_n, \ell)}{q_n(\ell)} \right)$$

for any distribution  $q_n(\cdot)$ .

Replacing with the right-hand side, we have:

$$\begin{aligned} \log P(\mathcal{D} | \pi, \Theta) &\geq \sum_n \sum_{\ell} q_n(\ell) \log \frac{p_{\ell}(\mathbf{x}_n | \theta_{\ell})}{q_n(\ell)} \\ &\geq \sum_{\ell} \left[ \sum_n q_n(\ell) \log \frac{p_{\ell}(\mathbf{x}_n | \theta_{\ell})}{q_n(\ell)} \right] = \mathcal{L} \end{aligned}$$

and therefore the optimisation w.r.to cluster parameters separate.

$$\partial_{\theta_{\ell}} \Rightarrow 0 = \sum_n q_n(\ell) \frac{\partial \log p_{\ell}(\mathbf{x}_n | \theta_{\ell})}{\partial \theta_{\ell}}$$

For distributions from exponential family optimisation is easy.

- **any** set of distributions  $q_1(\ell), \dots, q_N(\ell)$  provides a lower bound to the log-likelihood.
- We should choose the distributions so that they are the closest to the **current** parameter set.

**We assume** the **parameters** have the value  $\theta_0$ .

Want to minimise the difference:

$$\log P(\mathbf{x}_n, \ell | \theta_\ell^0) - \mathcal{L} = \sum_{\ell} q_n(\ell) \log P(\mathbf{x}_n, \ell | \theta_\ell^0) - \sum_{\ell} q_n(\ell) \log \frac{p_{\ell}(\mathbf{x}_n, \ell | \theta_\ell^0)}{q_n(\ell)}$$
$$\sum_{\ell} q_n(\ell) \log \frac{P(\mathbf{x}_n, \ell | \theta_\ell^0) q_n(\ell)}{p_{\ell}(\mathbf{x}_n | \theta_\ell^0)}$$

and observe that by **setting**

$$q_n(\ell) = \frac{p_{\ell}(\mathbf{x}_n | \theta_\ell^0)}{P(\mathbf{x}_n, \ell | \theta_\ell^0)}$$

we have  $\sum_{\ell} q_n(\ell) \theta = 0$ .

## The EM algorithm:

**Init** – initialise model parameters;

**E step** – compute the responsibilities  $\gamma_{nl} = q_n(\ell)$ ;

**M step** – for each  $k$  optimize

$$0 = \sum_n q_n(\ell) \frac{\partial \log p_\ell(\mathbf{x}_n | \boldsymbol{\theta}_\ell)}{\partial \boldsymbol{\theta}_\ell}$$

**repeat** – goto the **E step**.

# EM application

Probabilistic Data Mining

Lehel Csató
